HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.
MASC, a model to assess the sustainability of cropping systems:
Taking advantage of feedback from first users

The first version of MASC model (for Multi-attribute Assessment of the Sustainability of Cropping Systems) has been designed initially to select newly designed Cropping Systems (CS) before testing them in field trials (Sadok et al., 2009). Different users in the field of agriculture tested MASC in various contexts and commented its use and its usefulness. We recorded comments from these users in order to gain greater insight on their requested needs and in order to improve the model.

MASC is a qualitative multi-criteria model based on criteria that are hierarchically organized into a decision tree. These criteria are aggregated in order to assess the three usual dimensions of sustainability (economic, social and environmental). Two types of criteria can be distinguished in this tree (Figure 2):

- **Basic criteria** which correspond to the inputs of the decision tree (filled thanks to specific indicators).
- **Aggregated criteria** which are located at a higher level in the hierarchical tree, depending on those at lower levels.

Aggregations are based on weights (%) according to utility functions defined by “If-Then” decision rules.

After a test of the model in real situations for three years by various users, designers gathered feedback from them by organizing a workshop, sending out a survey, interviewing users and holding a consultation meeting.

### RESULTS

The model was used in somewhat differently than expected and lead to identify improvements:

- Users targeted much more varied purposes than the one initially planned by the model designers (Table 1).

  - A need for enlarging the scope of the model

- Users also led ex post assessment thanks to the simple indicators based on the description of planned practices.

  - A need of simple indicators to make easier & faster ex post assessment

- Users replaced the suggested indicators with better suited to their context (such as field measurements).

  - A need of flexibility to assess basic concerns

- Users modified the set of weights to integrate both local issues and their own perception of sustainability (Craheix et al. 2012)

  - A need of flexibility in parameter settings

- Users suggested new criteria to enhance the relevance of

  - A need of a more detailed analysis of the sustainability (Figure 2; Craheix et al., 2011)

### CONCLUSION

- Analysis of users’ feedback played a key role in the development of MASC 2.0.
- The main improvements have involved specifying the domain of validity, extending the range of concerns by adding new criteria, and enhance flexibility both appropriation by stakeholders and adaptations to the local socioeconomic and pedoclimatic context.
