Abstract. In order to correctly assess the nutritional quality of a meal or a manufactured food product in a given country, the first step is to assess the nutritional values for its ingredients. Food composition databases (FCDBs) available in a lot of countries and managed at national level provide values for energy and nutrients of food components. Unfortunately, values associated with some nutrients of interest may be lacking in the FCDB of the country in which the nutritional quality must be assessed. Finding values associated with nutrients for similar foods in other FCDBs is a way to deal with incompleteness. An additional issue arises because the vocabulary used to describe the ingredients of a meal or a recipe in a given FCDB is usually different from the one used in other ones. In this paper we address the problem of identifying the nutritional value of recipe's ingredients by querying different FCDBs through FoodOn as pivot ontology. We present a new alignment method between two distinct FCDBs, based on syntactic and semantic approaches, whose vocabulary is previously transformed into an ontology. Our method has been evaluated on Ciqual, the French food nutritional database, USDA, the United States food nutritional database and the FoodOn ontology. The incompleteness management task based on FoodOn as pivot ontology has been assessed with a real use-case concerning iron, Vitamin B12, Vitamin C nutrients.

Keywords. Ontology alignment, Food composition databases, FoodOn, LanguaL.

In the framework of the French Meatylab project including industrial partners, we were asked to propose a solution to combine data retrieved from several Food composition databases (FCDB) \cite{1} managed by different agencies and countries to assess the nutritional values of a recipe. Each agency has its own way of describing a food product, whether in terms of labeling or categorization in different. Unfortunately, values associated with some nutrients of interest may be lacking in the FCDB of the country in which the nutritional quality must be assessed. Finding values associated with nutrients for similar foods in other FCDBs is a way to deal with incompleteness. Consequently, our goal is to offer a multi-base query tool based on an ontology to establish links between similar foods. This functionality is not available in state of the art tools (eg. EuroFIR FoodExplorer).

As an example, this tool should be able to use a vocabulary concept (for example example ‘Courgette, puree’ from CIQUAL FCDB), to be able to recover all the products and associated nutritional values (e.g. ‘Squash, winter, acorn, cooked, boiled, mashed, without salt’ in USDA FCDB). To achieve this, we use as background knowledge, the LanguaL description [2] associated with the food term defined in each national agency. These descriptions provide a multi-facets semantic definition of a given food expressed in a standardized vocabulary that we will use to find similarities between food products belonging to the vocabulary of different agencies. Our method also takes into account English labels associated with food products in FCDBs. The pivot of all these vocabularies is FoodOn [3], an ontology dedicated to food description which includes a set of food products described with LanguaL (SIREN part of FoodOn).

Our approach aligns the food products of the different FCDBs on FoodOn, based on LanguaL faceted descriptions (semantic approach) in addition to product labels (syntactic approach). This combination of both approaches permits to overcome both the lack of faceted description for some products and the gaps in a purely syntactic comparison.

The main originality of our alignment approach is to reuse LanguaL descriptions associated with FCDBs food terms available on LanguaL website combining relevant alignment methods already known in the state of the art [4]. We will present main principles of the approach and results obtained to deal with Vit. C, Vit. B12, iron-lacking values for a set of Ciqual food products reusing values associated with similar foods in USDA.
